import sys, wget, tarfile, os
from pathlib import Path
import matplotlib.pyplot as plt
import numpy as np
import kornia
from fastai.vision import *
import warnings
warnings.filterwarnings('ignore')
```

We will be using in this colab, the Bottle Class.

```
data path=Path("/kaggle/input/bottle")
dset='bottle'
list((data path/dset/'train').glob('*'))
im paths=list((data path/dset/'train'/'good').glob('*'))
len(im paths) #How many examples do we have? (We have 209 images for
the train)
209
# The test folder has a bit more going on, and includes examples of a
3 defect
# classes, and some more good examples to use in testing.
list((data path/dset/'test').glob('*'))
[PosixPath('/kaggle/input/bottle/bottle/test/good'),
 PosixPath('/kaggle/input/bottle/bottle/test/contamination'),
PosixPath('/kaggle/input/bottle/bottle/test/broken_large'),
PosixPath('/kaggle/input/bottle/bottle/test/broken small')]
plt.imshow(plt.imread(str(im paths[0])))
plt.title('Bottle Image');
```

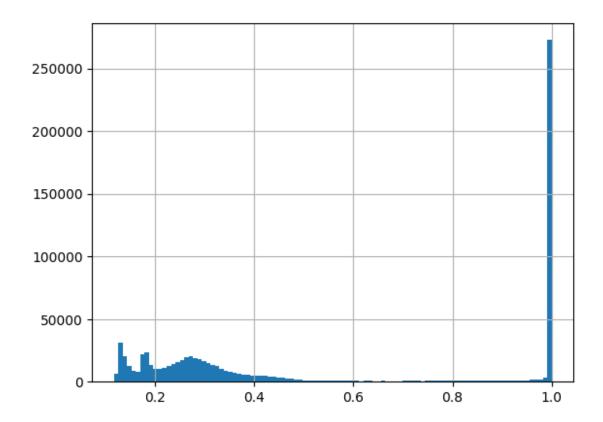

Now, we'll create a a dataloader that will return minibatches of size 128, downsample our images to 64x64. The databunch from the fastai library will take care of data augmentation and normalization.

Let's have a quick look at the scale of the data.

```
# Our GAN needs to learn to imitate this distribution.
x, y=data.one_batch()
plt.hist(x.numpy().ravel(),100); plt.grid(1)
```

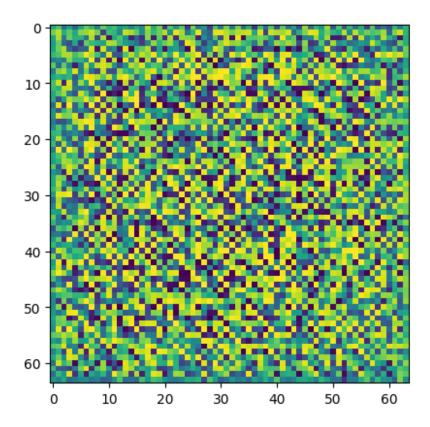

1. Creating Models

```
import torch
import torch.nn as nn
device = torch.device('cuda') if torch.cuda.is available() else
torch.device('cpu') #Do we have a GPU?
defaults.device = device
print(device)
cuda
def conv trans(ni, nf, ks=4, stride=2, padding=1):
    return nn.Sequential(
        nn.ConvTranspose2d(ni, nf, kernel_size=ks, bias=False,
stride=stride, padding=padding),
        nn.BatchNorm2d(nf),
        nn.ReLU(inplace = True))
G = nn.Sequential(
    conv_trans(100, 1024, ks=4, stride=1, padding=0),
    conv trans(1024, 512),
    conv trans(512, 256),
    conv trans(256, 128),
    nn.ConvTranspose2d(128, channels, 4, stride=2, padding=1),
    nn.Tanh()).to(device)
```

Let's test our Generator by creating a random vector and passing to the Generator!

```
z = torch.randn(1, 100, 1, 1)
fake = G(z.to(device))
plt.imshow(fake[0, 0].cpu().detach().numpy()); plt.grid(0)
```

Now, let's create the Discriminator.

```
def conv(ni, nf, ks=4, stride=2, padding=1):
    return nn.Sequential(
          nn.Conv2d(ni, nf, kernel_size=ks, bias=False, stride=stride,
padding=padding),
          nn.BatchNorm2d(nf),
          nn.LeakyReLU(0.2, inplace = True))

D = nn.Sequential(
    conv(channels, 128),
    conv(128, 256),
    conv(256, 512),
    conv(512, 1024),
    nn.Conv2d(1024, 1, 4, stride=1, padding=0),
    Flatten(),
    nn.Sigmoid()).to(device)
```

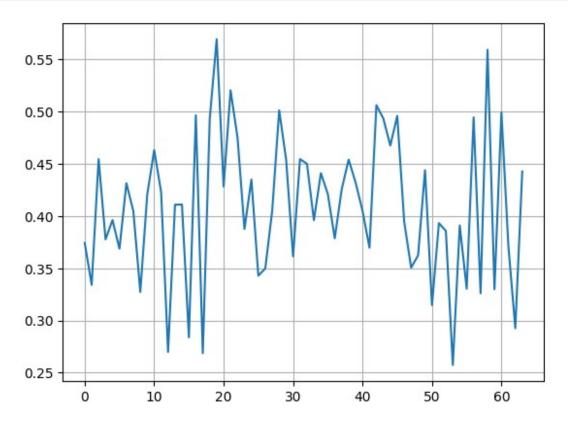

Let's try the Generator and the Discriminator!

```
fake=G(z.to(device))
D(fake)
tensor([[0.5618]], device='cuda:0', grad_fn=<SigmoidBackward0>)
```

The result we got, is the probability that the fake image is real.

For the training, we'll be passing in both real and fake data into our discriminator.

```
x,y=data.one_batch()
out=D(x.to(device))
plt.plot(out.detach().cpu()); plt.grid(1)
```

The outputs we've plotted are the probabilities of being real the discriminator has assigned to each image.

The results are wrong because we didn't train the discriminator yet.

2. Training

First, we'll choose randomly 25 points in our latent space. At each visualization step, we'll pass these 25 points through our generator, and see how our fake images look. As we train, our random noise should start to be shaped into hazelnuts!

Secondly, we'll plot a histogram of the pixel intensity of our fake images G(z) and compare these to our histograms of the pixel intensity values in our real images x. As we train, these distributions should look more and more similar.

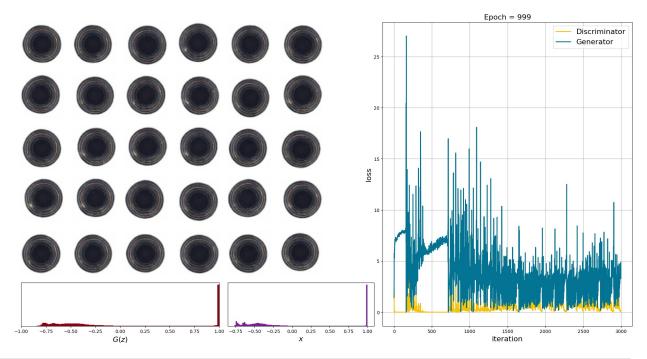

```
from torch import optim
from tgdm import tgdm
from IPython import display
import matplotlib.gridspec as gridspec
save training viz=True
save dir=Path('/kaggle/working/exports') #Location to save training
visualzations
(save dir/'viz').mkdir(exist ok=True, parents=True)
(save dir/'ckpts').mkdir(exist ok=True, parents=True)
def show progress(save=False):
    '''Visualization method to see how were doing'''
    plt.clf(); fig=plt.figure(0, (24, 12)); gs=gridspec.GridSpec(6,
12)
    with torch.no grad(): fake=G(z fixed)
    for j in range(30):
        fig.add_subplot(gs[(j//6), j%6])
        plt.imshow((kornia.tensor to image(fake[j])+1)/2);
plt.axis('off')
    ax=fig.add subplot(gs[5, :4]);
plt.hist(fake.detach().cpu().numpy().ravel(), 100,
facecolor='xkcd:crimson')
    ax.get_yaxis().set_ticks([]); plt.xlabel('$G(z)$', fontsize=16);
plt.xlim([-1, 1])
    ax=fig.add subplot(gs[5, 4:7]); plt.hist(x.cpu().numpy().ravel(),
100, facecolor='xkcd:purple')
    ax.get yaxis().set ticks([]); plt.xlabel('$x$', fontsize=16)
    fig.add subplot(gs[:,7:])
    plt.plot(losses[0], color='xkcd:goldenrod', linewidth=2);
plt.plot(losses[1], color='xkcd:sea blue', linewidth=2);
    plt.legend(['Discriminator', 'Generator'],loc=1, fontsize=16);
    plt.grid(1); plt.title('Epoch = ' + str(epoch), fontsize=16);
plt.ylabel('loss', fontsize=16); plt.xlabel('iteration', fontsize=16);
    display.clear output(wait=True); display.display(plt.gcf())
    if save: plt.savefig(save dir/'viz'/(str(count)+'.png'), dpi=150)
```

Now we'll setup our loss function and optimizers following the AnoGan Paper:

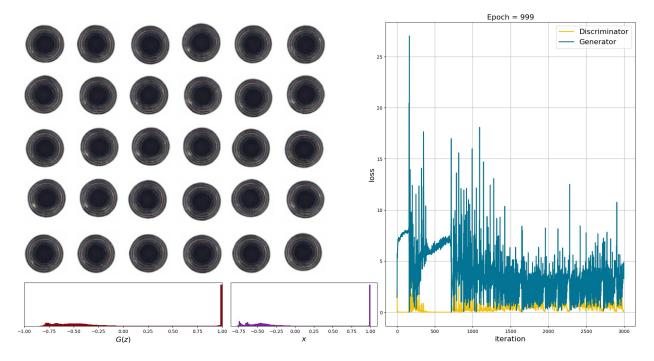

```
optD = optim.Adam(D.parameters(), lr=le-4, betas = (0.5, 0.999))
optG = optim.Adam(G.parameters(), lr=le-4, betas = (0.5, 0.999))
criterion = nn.BCELoss()

zero_labels = torch.zeros(batch_size).to(device)
ones_labels = torch.ones(batch_size).to(device)
losses = [[],[]]
```

```
epochs, viz freq, save freq, count = 1000, 100, 500, 0
z fixed = torch.randn(batch size, 100, 1, 1).to(device)
for epoch in range (epochs):
    for i, (x,y) in enumerate(tqdm(data.train dl)):
        #Train Discriminator
        requires_grad(G, False); #Speeds up training a smidge
        z = torch.randn(batch size, 100, 1, 1).to(device)
        l fake = criterion(D(G(z)).view(-1), zero_labels)
        l real = criterion(D(x).view(-1), ones labels)
        loss = l fake + l real
        loss.backward(); losses[0].append(loss.item())
        optD.step(); G.zero grad(); D.zero grad();
        #Train Generator
        requires grad(G, True);
        z = torch.randn(batch size, 100, 1, 1).to(device)
        loss = criterion(D(G(z)).view(-1), ones labels)
        loss.backward(); losses[1].append(loss.item())
        optG.step(); G.zero grad(); D.zero grad();
        if i%viz freq==0: show progress(save training viz)
        count+=1
    if (epoch+1)%save freq==0:
        torch.save(G, save dir/'ckpts'/('G epoch '+str(epoch)+'.pth'))
        torch.save(D, save_dir/'ckpts'/('D_epoch_'+str(epoch)+'.pth'))
```

<Figure size 640x480 with 0 Axes>

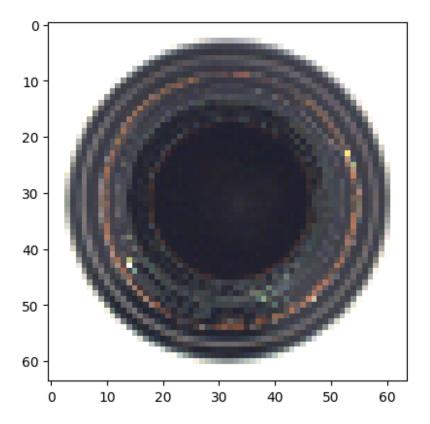

3. Using the Latent Space

Something interesting to know is that good images represent a manifold in a higher dimensional latent space of all images. This property can be used to detect anomalies!

Given a new image x, we're going to compute the representation of the image in our GANs latent space, and if our image is on the manifold of good iamges, we're going to call it good. And if it's too far from our manifold, we'll call it an anomaly.

But how can we find the representation of a new image in the latent space?

```
import cv2
im_path=(data_path/dset/'train'/'good').ls()[1]
im=cv2.cvtColor(cv2.imread(str(im_path)), cv2.COLOR_BGR2RGB)
im=cv2.resize(im, (64,64))
plt.imshow(im)
<matplotlib.image.AxesImage at 0x79448c30fee0>
```

We would like to know if how for from the manifold of good images in our Generator's latent space this image lies.

Unfortunately, we can't really compute this directly, but we can try to find the nearest point in our Generator's latent space and measure how far away this image is from that point, giving us an idea of how well this image "fits" with our good images.

We can find this nearest neighbor point using a very similar appraoch to our method for training our network. Specifically, we'll pick a random point in latent space, and using gradient descent, walk through latent space from that point guided by gradient descent.

As a loss function, we can use the l1 loss between our generated image and our "query" image.

$$L_R(z_y) = \sum |x - G(z_y)|$$

Let's give this a shot. We'll pick a random starting point and train for 1000 iterations to reduce the l1 loss between our query image and generated image.

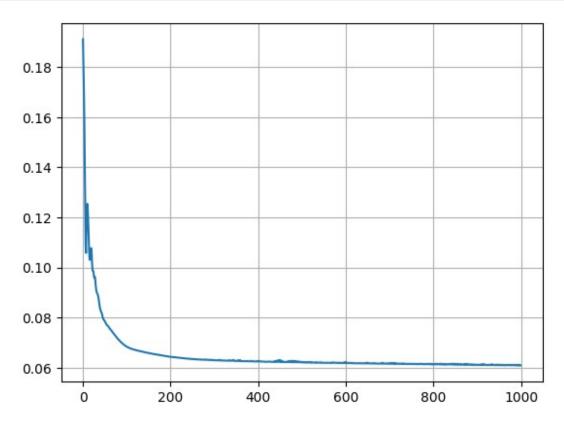

```
im_tensor=((kornia.image_to_tensor(im).float()/128)-1).to(device)
#Scale image between -1 and +1
z=torch.randn(1, 100, 1, 1, requires_grad=True, device=device) #Random
starting point in latent space
opt=optim.Adam([z], lr=2e-2)

losses=[]
for i in tqdm(range(1000)):
```

```
fake=G(z)
loss=torch.nn.L1Loss()(fake.squeeze(0), im_tensor)
loss.backward(); opt.step()
z.grad.zero_(); G.zero_grad()
losses.append(loss.item())

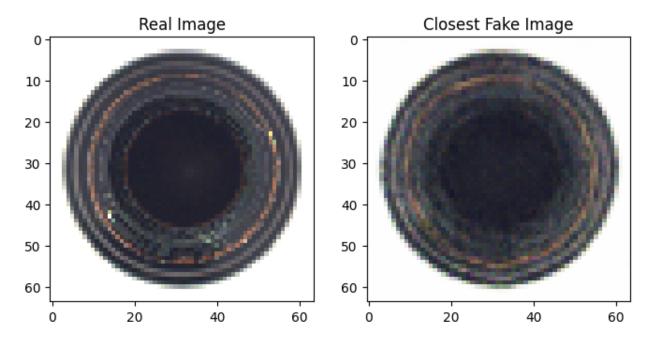

plt.plot(losses); plt.grid(1)

100%| 1000/1000 [00:05<00:00, 187.96it/s]</pre>
```

```
fig=plt.figure(0, (8,4))
fig.add_subplot(1,2,1)
plt.imshow(im); plt.title('Real Image')

fig.add_subplot(1,2,2)
plt.imshow((kornia.tensor_to_image(G(z))+1)/2); plt.title('Closest Fake Image')
Text(0.5, 1.0, 'Closest Fake Image')
```

The AnoGan authors use one more trick to get better results in finding the closest fake image. As you can imagine, this "optimizing backwards accross our generator" is far from a perfect science. The AnoGAN authors chose to use the discriminator to help the optimization land on a more realistic nearest good image. Specifically, they choose to add a term to the loss function that measures the distance between the discriminator's representation of the real and fake images.

We're going to compare the representation of the real and fake images in the feature space of the discriminator. The idea here is that through the training process the discriminator has learned lots of useful features to measure the perceptual difference between real and fake images. Techniques like this are called **perceptual loss**. The AnoGAN authors again use L1 loss, as shown in the equation below:

$$L_{D}(z_{y}) = \sum |f(x) - f(G(z_{y}))|$$

where $f(\cdot)$ represents the intermediate layers of the discriminator.

```
# Let's create a method that computes the discriminator feature loss
loss given a fake image
def get_d_loss(f_x, fake, D):
    loss_d=nn.L1Loss()(f_x[1], D[:1](fake)) #Get loss value from 1st
layer of D
    for i in range(2, (len(D)-2)):
        loss_d+=nn.L1Loss()(f_x[i], D[:i](fake)) #And remainig layers
of D
    return loss_d

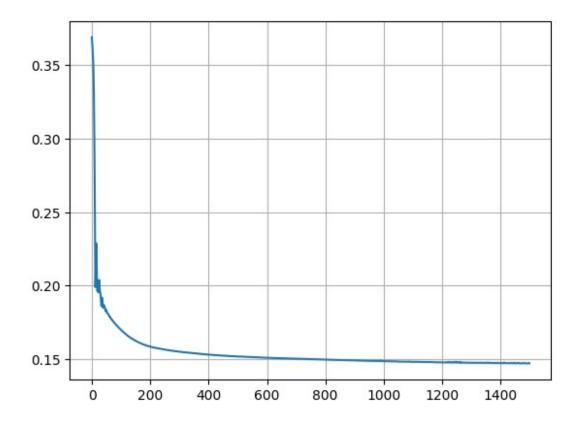

f={} #Precompute feature values for layers
with torch.no_grad():
    for i in range(1, (len(D)-2)): f[i]=D[:i](im_tensor.unsqueeze(0))
```

Finally, we need to balance our two loss terms (or reconstruction loss and discrminator loss). The AnoGan authors capture this in this equation:

$$L(z_{v}) = (1 - \lambda) \cdot L_{R}(z_{v}) + \lambda \cdot L_{D}(z_{v}).$$

Where $L(z_y)$ is our overall loss function value, and λ conrols the balance between our generator and discriminator loss.

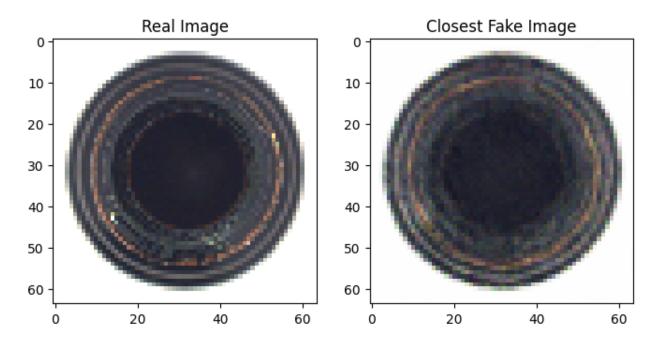

```
def walk latent space(G, D, im tensor, n iter=1500, lambd=0.1, lr=2e-
2, device='cuda'):
    f x={} #Precompute feature values all layers of D
    with torch.no grad():
        for i in range(1, (len(D)-2)): f x[i]=D[:i]
(im tensor.unsqueeze(⊙))
    z=torch.randn(1, 100, 1, 1, requires grad=True, device=device)
#random starting point for walk
    opt=optim.Adam([z], lr=lr)
    losses=[]
    for i in tqdm(range(n iter)):
        fake=G(z) #Get fake image
        loss r=torch.nn.L1Loss()(fake.squeeze(0), im tensor) #Residual
loss
        loss d=qet d loss(f x, fake, D) #Discrimintator loss
        loss=(1-lambd)*loss r+lambd*loss d #Total loss
        loss.backward(); opt.step()
        z.grad.zero_(); G.zero_grad(); D.zero_grad();
        losses.append(loss.item())
    return {'z':z, 'loss':loss.item(), 'loss r':loss r.item(),
'loss d':loss d.item(), 'losses':losses}
im path=(data path/dset/'train'/'good').ls()[1]
im=cv2.cvtColor(cv2.imread(str(im path)), cv2.COLOR BGR2RGB)
im=cv2.resize(im, (64,64))
im_tensor=((kornia.image_to_tensor(im).float()/128)-1).to(device)
res=walk_latent_space(G, D, im_tensor, n_iter=1500, lambd=0.1, lr=2e-
2, device='cuda')
# Let's plot the loss.
plt.plot(res['losses']); plt.grid(1)
100% | 1500/1500 [00:17<00:00, 87.92it/s]
```

Finally, let's see the result.

```
fig=plt.figure(0, (8,4))
fig.add_subplot(1,2,1)
plt.imshow(im); plt.title('Real Image')

fig.add_subplot(1,2,2)
plt.imshow((kornia.tensor_to_image(G(res['z']))+1)/2);
plt.title('Closest Fake Image')
Text(0.5, 1.0, 'Closest Fake Image')
```

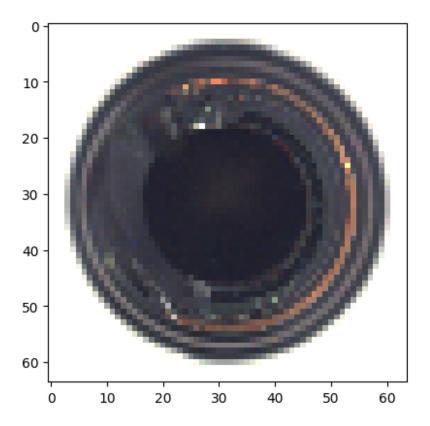

4. Finding Anomalies

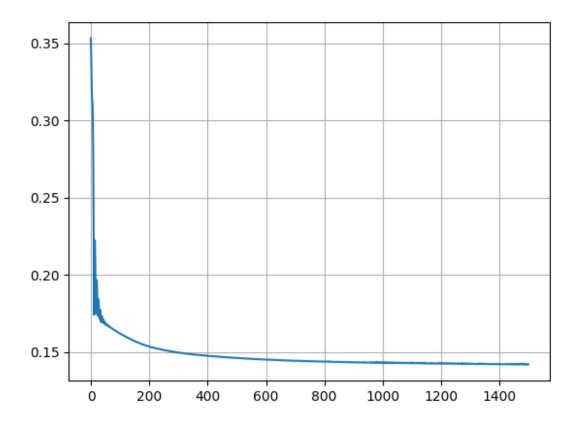

Now, we finally have all the pieces we need to find anomalies using our GAN. To see how this works, let's grab an image with some anomalies.

```
im_path=Path('/kaggle/input/bottle/bottle/test/broken_large/010.png')
im=cv2.cvtColor(cv2.imread(str(im_path)), cv2.COLOR_BGR2RGB)
im=cv2.resize(im, (64,64))
plt.imshow(im)

<matplotlib.image.AxesImage at 0x7944ca8521d0>
```

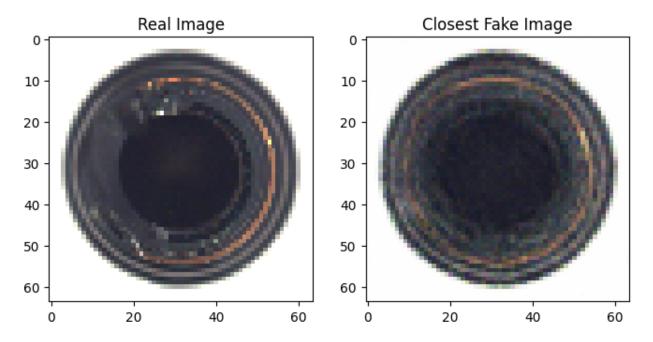

The anogan idea here is that anomalous images like this shouldn't really exist in the latent space of our Generator, since we only trained it on good images. So when we try to reconstruct our anamolous image, the reconstruction should fail.

Alright, let's have a look at our reconstructed image:

```
fig=plt.figure(0, (8,4))
fig.add_subplot(1,2,1)
plt.imshow(im); plt.title('Real Image')

fig.add_subplot(1,2,2)
plt.imshow((kornia.tensor_to_image(G(res['z']))+1)/2);
plt.title('Closest Fake Image')
Text(0.5, 1.0, 'Closest Fake Image')
```

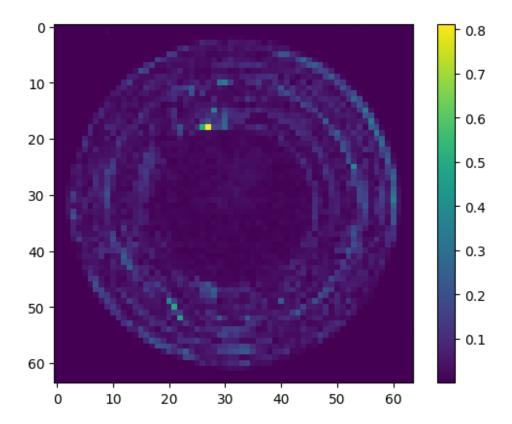

As we can see, the reconstruction isn't great. The Generator shouldn't be able to reconstruct anomolous images. The idea, now, is to measure how poor the reconstruction is, to measure how anamolous the image is. (We will be setting a certain threshold)

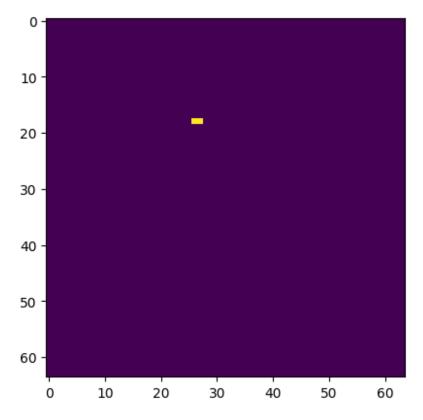

As a metric, it is possible to use the reconstruction loss $L_R(z_y)$ and the discriminator loss $L_D(z_y)$. If these losses are high, then we are dealing with an anomalous image.

The AnoGan paper introduced, in addition to this anomaly detection technique, a technique to localize the anomaly. Researchers suggested to compute a residual image (the difference between the original and the reconstructed image) and areas of the residual image with large values should correspond to anomalous regions, since the original and reconstructed image are maxiamlly different in these regions.

```
xr=np.abs((im.astype('float')/255)-(kornia.tensor_to_image(G(z))+1)/2)
#Residual image
plt.imshow(np.mean(xr, axis=2))
plt.colorbar()
<matplotlib.colorbar.Colorbar at 0x7944caa633d0>
```

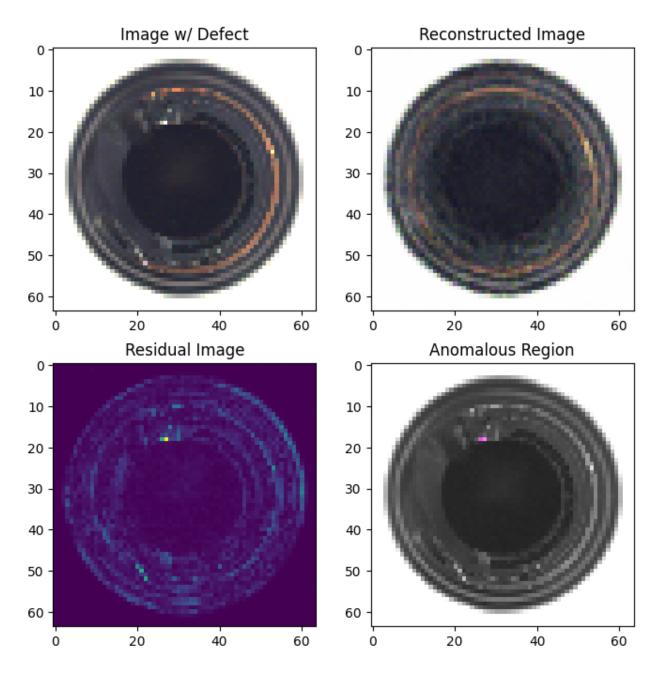

Let's identify anomalous pixels
thresh=0.5
plt.imshow(np.mean(xr, axis=2)>thresh)
<matplotlib.image.AxesImage at 0x79448775dcc0>

```
# As a result, we are getting
im_mask=np.zeros_like(im)
for i in range(3): im_mask[:,:,i]=np.mean(im, axis=2)
im_mask[np.mean(xr, axis=2)>thresh]=im_mask[np.mean(xr, axis=2)>thresh]//2+np.array([255,0,255])//2

fig=plt.figure(0, (8,8))
fig.add_subplot(2,2,1); plt.imshow(im); plt.title('Image w/ Defect')
fig.add_subplot(2,2,2);
plt.imshow((kornia.tensor_to_image(G(res['z']))+1)/2);
plt.title('Reconstructed Image')
fig.add_subplot(2,2,3); plt.imshow(np.mean(xr, axis=2));
plt.title('Residual Image')
fig.add_subplot(2,2,4); plt.imshow(im_mask); plt.title('Anomalous Region')

Text(0.5, 1.0, 'Anomalous Region')
```

Now, let's loop over all of the test images, and for each we'll create a reconstructed image, and compute the reconstruction and discriminator loss for each image.

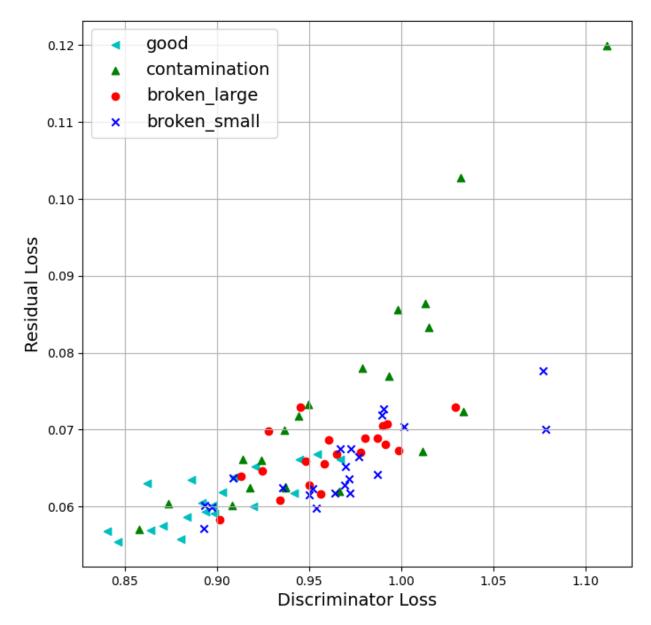

```
params={'n_iter':1500, 'lambd':0.1, 'lr':2e-2}
all_res=[]
im_paths=[p for p in (data_path/dset/'test').glob('*/*.png')]
for im_path in im_paths:
    im=cv2.cvtColor(cv2.imread(str(im_path)), cv2.COLOR_BGR2RGB)
    im=cv2.resize(im, (64,64))

im_tensor=((kornia.image_to_tensor(im).float()/128)-1).to(device)
```

```
res=walk latent space(G, D, im tensor, **params, device=device)
    res['im fake']=(kornia.tensor_to_image(G(res['z']))+1)/2 #Scaled
between 0 and 1
    res['im path']=im path
    res['label']=im path.parent.name
    all res.append(res)
                 1500/1500 [00:17<00:00, 87.79it/s]

    handles[res['label']]=plt.scatter(res['loss_d'], res['loss_r'],
    c=my_cmap[cm[res['label']]], marker=my_markers[cm[res['label']]])
    plt.legend(handles=handles.values(), labels=handles.keys(),
    fontsize=14); plt.grid(1)
    plt.xlabel('Discriminator Loss', fontsize=14)
    plt.ylabel('Residual Loss', fontsize=14)
Text(0, 0.5, 'Residual Loss')
```

Since the generator should find it more difficult to reproduce anomlous images, we should see a higher reconstruction loss for the anomolous images, relative to the good images. As we can see, this isn't really true, with the good images having medium to high reconstruction losses.

However, we do see a pretty reasonable pattern with our discriminator loss, anomalous images tend to have higher discriminator losses. We can use this to create an anomalous image detector.

Something more complicated that can be done is to classify anomolous images in the space of the discriminator and residual loss using some neural networks.

```
def anomaly_detector(im, G, D, d_loss_thresh, r_loss_thresh):
    '''Decides if image im is anomalous'''
    im_tensor=((kornia.image_to_tensor(im).float()/128)-1).to(device)
    res=walk_latent_space(G, D, im_tensor, n_iter=1500, lambd=0.1,
lr=2e-2, device='cuda')
    if res['loss_d']>d_loss_thresh or res['loss_r']>r_loss_thresh:
return True
    else: return False
```

Here, we'll choose a d_loss_thresh of 1.3, and a r_loss_thresh value of 0.21.

Let's measure the accuracy of the anomaly detector:

```
num_correct=0; total=0 #Measure accuracy on good test examples
for im_path in (data_path/dset/'test'/'good').glob('*.png'):
   im=cv2.cvtColor(cv2.imread(str(im path)), cv2.COLOR BGR2RGB)
   im=cv2.resize(im, (64,64))
   predicted anomaly=anomaly detector(im, G, D, d loss thresh=1.3,
r loss thresh=0.21)
   if not predicted anomaly: num correct+=1
   total+=1
   print(im path, predicted anomaly)

47%|
               | 702/1500 [00:07<00:09, 85.96it/s]
num_correct/total
num correct=0; total=0 #Measure accuracy on defective test examples
for im_path in (data_path/dset/'test').glob('*/*'):
   if 'good' in str(im path): continue
   im=cv2.cvtColor(cv2.imread(str(im path)), cv2.COLOR BGR2RGB)
   im=cv2.resize(im, (64,64))
   predicted anomaly=anomaly detector(im, G, D, d loss thresh=1.3,
r_loss_thresh=0.21)
   if predicted anomaly: num correct+=1
   total+=1
   print(im_path, predicted_anomaly)
num correct/total
```

For comparison, the MVTec AD paper sites an accruacy on hazelnuts using AnoGAN of 0.83 for the good examples, and 0.16 for the anamolous examples.
